Lab 10 – Procedures and Stacks

Anubhav Elhence

What are Procedures?

- ▶ Procedure is a part of code that can be called from your program in order to make some specific task. Procedures make program more structural and easier to understand. Generally procedure returns to the same point from where it was called.

- ▶ The syntax for procedure declaration:

```
name PROC  
    ; here goes the code  
    ; of the procedure ...  
RET  
name ENDP
```

- ▶ (name - is the procedure name); The same name should be used for both the PROC and ENDP directives! (This is used to check the correct closing of procedures)
- ▶ PROC and ENDP are compiler directives, so they are not assembled into any real machine code. The compiler just remembers the address of the procedure.

The Call Instruction

- ▶ The `CALL` instruction is used to call a procedure. The `RET` instruction is used to return to the operating system. The same instruction is used to return from a procedure (actually, the operating system sees your entire program as a special procedure).
- ▶ For example, in the code below, the program calls the procedure `m1`, performs `MOV BX, 5`, and proceeds to the next instruction (`MOV AX, 2`)

```
ASM week10_c1.asm > ...
1  .model tiny
2  .data
3
4  .code
5  .startup
6
7  CALL m1
8  MOV AX, 2h
9  RET
10
11  m1 PROC
12      MOV BX, 5h
13  RET
14  m1 ENDP
15
16
17  .exit
18  end
```

6 references

The Call Instruction

- ▶ For example, in the code below, the program calls the procedure m1, performs MOV BX, 5, and proceeds to the next instruction (MOV AX, 2)

ASM week10_c1.asm > ...

```
1  .model tiny
2  .data
3
4  .code
5  .startup
6
7  CALL m1
8  MOV AX, 2h
9  RET
10
11  m1 PROC
12      MOV BX, 5h
13  RET
14  m1 ENDP
15
16
17  .exit
18  6 references
19  end
```

```

Passing parameters to Procedures

ASM week10_c2.asm > ...

```
1  .model tiny
2  .data
3
4  .code
5  .startup
6      MOV AL, 1
7      MOV BL, 2
8
9      CALL m2
10     CALL m2
11     CALL m2
12     CALL m2
13     RET
14
15     m2 PROC
16     MUL BL
17     RET
18     m2 ENDP
19
20
21 .exit
22 6 references
23 end
```

► There are several ways to pass parameters to a procedure. The easiest way to pass parameters is by using registers. Here is another example of a procedure that receives two parameters in AL and BL registers, multiplies these parameters, and returns the result in AX register. Since m2 is called four times, the final result in AX will be $2h^4h$ (10H)

; Return to the OS

; The product of AL, BL is stored in AX
; Return to the Caller

Stack

- ▶ The Stack is an area of memory for keeping temporary data. The stack is used by the `CALL` instruction to keep return address for procedure, and the `RET` instruction gets this value from the stack and returns to that offset.
- ▶ This also happens when `INT` instruction calls an interrupt (Recall `INT 21h` and `INT 10h`!). It stores the code segment and offset in the stack flag register. Similar to `RET`, the `IRET` instruction is used to return from interrupt call.

Push and Pop Instr

- ▶ The stack is a LIFO data structure (Last In, First Out) can be accessed to store or retrieve data using these two instructions-
- ▶ `PUSH` - stores a 16 bit value (from a register or memory location) in the stack.
- ▶ `POP` - gets 16 bit value from the stack and stores it in a register or a memory location.

Syntax:

`PUSH REG` ; AX, BX, DI, SI etc.
`PUSH SREG` ; DS, SS, ES etc.
`PUSH memory` ; [BX], [BX+SI] etc.
`PUSH immediate` ; 5, 3Fh, 10001000b etc.

Syntax:

`POP REG` ; AX, BX, DI, SI etc.
`POP SREG` ; DS, SS, ES etc.
`POP memory` ; [BX], [BX+SI] etc.

Follow along example

- ▶ The following example shows how the stack can be used to swap the values in the registers AX and BX. Notice the order of registers in the pop operation!

```
ASM wee10_c3.asm > ...
1  .model small
2  .data
3
4  .code
5  .startup
6      MOV AX, 1212h
7      MOV BX, 3434h
8
9      PUSH AX
10     PUSH BX
11
12     POP AX
13     POP BX
14
15
16
17 .exit
18 4 references
19 end
```

Thankyou
